Tabmac: Overview

Tabmac turns dining consumption into a subscribable, distributable, and fulfillable demand network that connects consumers, businesses, and restaurants.

Tabmac: Why Dining Subscription Is More Than a Membership Benefit

Reorganizing fragmented dining consumption into a reusable dining credit network.

Dining is not naturally a subscription-based behavior. Most dining decisions happen as separate moments: what to eat today, which restaurant to choose, how much to spend, and whether a new place is worth trying.

Tabmac's opportunity was not to add another membership layer for restaurants, but to reorganize fragmented dining consumption into a subscription model. Through tiers and dining credits, users are buying dining capacity that can be used continuously across a partner restaurant network.

So Tabmac is not fundamentally about selling plans. It is about building a subscription-based dining network.

Tabmac: Putting Consumers, Businesses, and Restaurants into One Value Chain

One dining credit network puts three roles into the same growth logic.

Tabmac's business logic is not about serving consumers, businesses, and restaurants separately. It is about putting them into the same value chain through one dining credit network.

Platform value comes from the way these roles strengthen one another: credits create sustained demand, more demand attracts more restaurants, and more restaurants make subscriptions and business purchasing more valuable.

Tabmac: From Unclear Value to Broken Fulfillment

Comprehension, redemption, business purchasing, and restaurant fulfillment form one continuous chain.

When mapping Tabmac's use cases, I treated the problem as one continuous chain: whether users understand the subscription value, whether they can redeem with low friction, whether businesses can purchase and distribute, and whether restaurants can fulfill smoothly.

The first break happens in value comprehension. The second break happens during in-store redemption. Organizational purchasing then needs budget, member, distribution, and usage control. Restaurant fulfillment also has to stay light enough to avoid staff explanation and backend maintenance cost.

Tabmac: Breaking Down the Failure Points

Turning value explanation, control, redemption, and fulfillment into designable modules.

The breaks pointed to one product judgment: for subscription to work, value explanation, organizational control, redemption paths, and restaurant fulfillment have to be handled by the same system.

Subscription Value Needs Explanation

Users need to understand tiers, dining credits, and available restaurants, not only discount descriptions.

Business Purchasing Needs Control

Budget, members, distribution rules, and usage records need to sit in one management model.

Redemption Cannot Be Heavy

In-store scenarios need low-friction redemption without forcing install, signup, or complex rule learning.

Restaurant Fulfillment Needs to Stay Light

Restaurants need stable demand while reducing staff explanation and backend maintenance cost.

Tabmac: Core Hypothesis: Use Subscription to Connect Discovery, Redemption, and Fulfillment

Subscription is not only a purchase entry point. It is the system foundation.

If Tabmac can use tiers and dining credits to create a clear dining value structure, and keep credits consistent across consumer use, business distribution, and restaurant fulfillment, then subscription becomes more than a purchase entry point. It becomes the system foundation that connects demand, supply, and fulfillment.

Clear Credit Model

Help users understand tiers, dining credits, and available scope as they enter the flow.

Low-friction Fulfillment

Redemption, checkout, and tips need to fit real in-store scenarios.

Organizational Control

Business purchasing needs to cover purchase, distribution, teams, and usage tracking.

Restaurant-side Value

Restaurants need to see compound demand from subscription, business, and venue use cases.

Ecosystem Growth Loop

Each module should strengthen the subscription network and restaurant supply.

Tabmac: V1: Making the Consumer Loop Clear First

First validate whether users can understand subscription, discover restaurants, and complete redemption.

Main

Make restaurants, tiers, and available dining credits visible directly on the home screen.

Map

Use location to turn subscription benefits into real in-store choices.

Store

Centralize available items, rules, and redemption entry points on the store page.

Account

Unify plans, dining credits, rewards, and business-distributed benefits.

The first version of Tabmac first validated the consumer loop: whether users could understand the subscription and credit model, discover available restaurants, confirm what they could use, and complete redemption or payment before or after the visit.

The main interface needed to turn dining subscription into concrete choices. Users should see restaurants, tiers, available dining credits, and action entry points instead of abstract membership benefits. The account page provides one stable place to review plans, credits, rewards, and business-distributed benefits.

Tabmac: Turning Business Purchasing into a Manageable Workflow

Extending the same dining credits into organizational purchasing and benefit distribution.

Business is not a separate enterprise backend. It extends the same dining credits from individual consumption into organizational purchasing and benefit distribution.

When a company buys dining benefits, the most complex part is not payment. It is what happens after purchase: how benefits are distributed, whether purchases recur, how members use them, and how admins review usage. I separated Bulk Purchase, Recurring Purchase, Distribution, and Teams into clear management tasks instead of compressing every setting into one checkout form.

Business needs not only purchase entry points, but also a management structure after purchase.

Admins can complete bulk or recurring purchase first, then decide recipients and team scope. This keeps purchase behavior and organization management separate enough to understand, while making later tracking easier.

Bulk Purchase

Purchase dining credits or subscriptions in bulk by headcount, budget, or benefit type.

Recurring Purchase

Support recurring distribution so dining benefits keep entering the organization workflow.

Distribution

Distribute purchase results by member, team, or rule.

Teams

Use organization structure to support budgets, members, and usage records.

Show more

Tabmac Venue borrows the structure of hotel booking: choose a venue, time, and party size, review capacity, rules, and pricing, then move toward confirmation. Instant Quote turns conditions that used to require multiple rounds of communication into a structure users can evaluate upfront.

Tabmac: Venue Mechanism Breakdown

Reducing low-certainty communication and moving requests closer to a bookable state.

The key to Venue is not moving a private dining form online. It is turning capacity, time, minimum spend, and rules into a quote structure that users can evaluate upfront, while restaurants preserve control through configurable rules.

Venue Discovery

Help users understand space, capacity, constraints, and use cases first.

Instant Quote

Move pricing and rules earlier to reduce low-certainty back-and-forth communication.

Restaurant Control

Let restaurants preserve control over quote and availability through configurable rules.

Tabmac: Making Checkout and Redemption Low-friction Entry Points

Checkout, Redeem, and Tips reduce friction around in-store fulfillment.

Checkout

Use App Clips to lower the barrier for first-time payment.

Redeem

Let subscriptions, campaigns, and business-distributed benefits share one redemption path.

Tips

Integrate tips, business policy, and final payment confirmation into one flow.

In an in-store context, users have little patience. If checkout, redemption, or tipping requires installing the full app, creating an account, or learning complex rules, it directly hurts completion and increases staff explanation cost.

Tabmac Checkout and Redeem were designed as lightweight entry points. With App Clips, users without the full app can still complete payment. Tips sit in the same flow as business policy, restaurant settings, and user confirmation.

Tabmac: From a Feature Set to a Dining Demand System

Subscription, Business, Venue, and fulfillment connect into one growth structure.

The final Tabmac design is not a feature set. It is a dining demand system that runs around dining credits.

The demand foundation is subscription and dining credits. Demand expansion comes from Business and Venue. Business purchasing brings dining budgets into organizational contexts, while venue booking brings team events and business demand into the restaurant network. Checkout, Redeem, and Tips reduce friction around in-store payment, benefit redemption, and service-rule confirmation.

Tabmac: What Tabmac Solves

Different roles complete their goals around the same dining credit, supply, and fulfillment system.

Tabmac ultimately solves more than single-screen efficiency. It helps different roles complete their goals around the same dining credits, supply, and fulfillment system.

Consumer

Understand and use diverse dining choices with lower effort.

Business

Bring dining benefits into a purchasable, distributable, and trackable organizational workflow.

Restaurant

Use one entry point to receive subscription, business, venue, and in-store fulfillment demand.

Platform

Let dining credits, supply, business budgets, and fulfillment modules drive one another's growth.

Tabmac: A Subscription Platform Has to Fulfill Its Value

17

Reflection: subscription is not a pricing bundle, but a structure for value, delivery, and growth.

Tabmac changed how I understand subscription product design. A subscription is not just a pricing bundle, and it is not solved by adding more membership benefits to a page. The difficult part is using tiers and quotas to create a value structure that feels clear enough for users, controllable enough for businesses, and valuable enough for restaurants to join.

If viewed only from the consumer side, the problem looks like restaurant discovery and redemption. If viewed only from the business side, it becomes procurement and distribution tooling. If viewed only from the restaurant side, it becomes backend and payment efficiency.

The Tabmac logo is centered on a solid blue rectangular background. The logo itself consists of a stylized, white, handwritten-style 'T' followed by the word 'abmac' in a clean, white, sans-serif font.

Treeing: Overview

Treeing helps travelers return to trusted hosts and helps hosts maintain repeat-guest relationships efficiently.

Treeing: Why Travel Booking Needs a Relationship Layer

Traditional platforms focus on listing inventory, but overlook long-term trust between travelers and hosts.

Traditional travel booking platforms usually start with inventory. This model works for first-time exploration, but it is not the best fit for repeat booking once trust already exists.

A traveler may remember a good stay, a host who communicated clearly, or another property managed by the same host. But on most platforms, this relationship cannot be saved as a stable entry point. Treeing's opportunity is to structure the existing trust between hosts and returning travelers.

Treeing: Turning Repeat-Guest Relationships into Shared Value

Traveler, host, and platform value come from the same relationship network.

Treeing's business logic is built around value for travelers, hosts, and the platform. For travelers, Treeing reduces repeated decision cost. For hosts, Treeing reduces the cost of repeat-guest operations. For the platform, Treeing's value is not only listing inventory. It is the relationship network.

Traveler Value

Return to trusted hosts quickly and reduce repeated search.

Host Value

Manage repeat guests in one place and increase repeat booking.

Platform Value

Turn relationships into a platform asset and improve retention.

Treeing: From Search Pressure to Operational Burden

Complex traveler search and high host maintenance cost became the core design problem.

When mapping traveler and host scenarios, I separated the problem into two types: one before booking, and one during long-term operations. On the traveler side, the core problem is search pressure and trust transfer. On the host side, the core problem is relationship management and maintenance cost.

Repeated Traveler Search

Trusted hosts rarely become the next booking entry point.

Trust Cannot Be Saved

Users remember the experience, but the platform does not create a return path.

Scattered Host Guests

Repeat guests come from many channels without one management model.

High Maintenance Cost

Pricing, dates, and availability need to be adjusted repeatedly across places.

Treeing: Core Hypothesis: Make Relationships the Booking Entry Point

Trusted relationships can shorten traveler paths and reduce host operational cost.

If Treeing can turn the trust between hosts and repeat guests into a discoverable, manageable, and bookable product structure, travelers can complete trusted bookings faster, while hosts can maintain repeat-guest relationships with less effort.

Relationship-first

Design around trust relationships, not listing grids.

Low Adoption Cost

Hosts can use Treeing without abandoning existing channels.

Operational Clarity

Hosts understand status quickly and complete maintenance.

Treeing: V1: Validating Whether Repeat-Guest Relationships Can Become a Booking Entry Point

23

V1 focused on whether repeat-guest relationships could shorten the booking path and reduce search pressure.

The first version of Treeing did not try to cover a full travel booking platform. It tested a more specific question first: when trust already exists between a traveler and a host, can the platform turn that relationship into a shorter and more natural booking path?

The V1 priorities centered on three areas: travelers needed an entry point back to trusted hosts; hosts needed a basic model for managing repeat guests; and the host side had to stay lightweight.

Treeing: Reducing Traveler Search Pressure

A lightweight recommendation queue and step-by-step mobile search reduce small-screen decision pressure.

Spotlight

Use a recommendation queue to reduce early filtering pressure.

Mobile Search

Step-by-step decisions: destination, dates, and party size.

Mobile Listing

Keep listing information, pricing, and action entry clear on small screens.

Traditional search asks users to define destination, dates, budget, room type, and preferences upfront, but many travel decisions do not start that way. Spotlight was designed as a lightweight recommendation queue.

Mobile Search uses a step-by-step flow instead of compressing a desktop search bar into a phone layout. Destination, dates, and party size are split into separate pages or modal layers, so users handle one question at a time.

Treeing: Productizing Repeat-Guest Relationships: Guest List and Invitation

Relationships are managed first, then explained as value users want to join.

Join the Guest List

First time to know Treeing?
[About Treeing](#)

Invitation

Show the joining value first, then guide the action.

Treeing's core is not Guest List as a single feature. It is the relationship layer built around it. For hosts, Guest List is a relationship management model that turns repeat guests scattered across channels into a manageable audience.

The invitation flow is important here. Users are not directly asked to join a list. They first see the value of joining Guest List: easier return visits to trusted hosts, potential access to better prices or dedicated content, and less search cost for the next booking.

Treeing: Productizing Repeat-Guest Relationships: Host Page and My Hosts

Relationships need to become stable, revisit-worthy entry points on the traveler side.

Host Page

Elevate the host into a revisit-worthy destination.

My Hosts

Make trusted hosts and their listings easy to access.

For travelers, the relationship needs to become visible after joining Guest List. The My Hosts area provides a long-term entry point for returning to trusted hosts. Host Page elevates the host from the operator behind a listing into a destination that can be followed, understood, and revisited.

This makes a trusted host more than a contact inside one past booking. It becomes a repeatable destination for future trips.

Treeing: Reducing Host Operational Cost: Dashboard and Listing Editing

27

Daily operating signals need to be visible at a glance, and editing should stay close to the final result.

Dashboard

Make key information visible at a glance.

Listing Editing

Let hosts edit listings inside a page close to the final presentation.

If Treeing improved only the traveler experience without reducing host maintenance cost, the platform would be difficult to sustain. Host Dashboard was designed as a daily workspace, not just a data display page. Key business signals, booking status, and schedule information are visible as soon as hosts enter the page.

Listing Editing uses a direct-editing approach close to the traveler view, reducing the mental distance between setup and outcome.

Treeing: Reducing Host Operational Cost: Batch Set and Calendar Connect

Batch rules and external sync reduce multi-listing, multi-platform maintenance burden.

Batch Set

Batch-adjust pricing and availability.

Calendar Connect

Sync external calendars to reduce maintenance cost.

Batch Set and Calendar Connect address multi-listing and multi-platform operations. Batch Set turns repeated price and availability adjustments into batch rules. Calendar Connect lowers adoption cost by syncing with external platforms.

Treeing's goal is not to ask hosts to abandon existing channels, but to become an easier relationship layer for repeat booking.

Treeing: From a Feature Set to a Relationship-based Booking System

Features connect through the relationship chain to form a repeatable, operationally sustainable system.

The final Treeing design is not a collection of separate features. It is a product system that operates around relationships.

The traveler side supports discovery and return visits. Spotlight reduces early exploration pressure, while My Hosts and Host Page turn trusted hosts into returnable entry points. The host side supports relationship management and operational maintenance through Guest List, Dashboard, Listing Editing, Batch Set, and Calendar Connect.

Treeing: What Treeing Solves

Design value can be understood from the traveler, host, and platform perspectives.

Treeing's design value can be understood from the traveler, host, and platform perspectives. For travelers, it reduces the cost of starting every trip from zero. For hosts, it turns repeat-guest relationships into a manageable asset. For the platform, it extends value from listing inventory to the relationship network.

Traveler

Reduce repeated search cost and create a repeat-booking path.

Host

Lower multi-listing and multi-platform maintenance cost, and provide a place to manage repeat guests.

Platform

Move from one-time transactions toward relationship-driven repeat booking.

Treeing: Travel Platforms Are Not Only Search

31

Reflection: the design focus is how relationships become booking entry points, not single-screen optimization.

Treeing changed how I understand the design focus of travel booking products. At first, the project looked like a listing marketplace, but the real complexity was not showing more listings. It was deciding what the platform should build long-term value around.

If viewed only from the traveler side, the problem looks like a search experience issue. If viewed only from the host side, it becomes a backend efficiency issue. Treeing's key insight is that these two problems are two ends of the same system.
